

Project 5, deadline December 9, 2016

Astronomy project, N -body simulation of an open galactic cluster

Fall semester 2016

Theoretical background and description of the system

The goal of this project is to develop a code that can perform simulations of an open cluster using Newtonian gravity. This project is inspired by an article by [M. Joyce and co-workers](#), see also the references below. When solving this project, we recommend downloading this article. It is a good companion to understand the physics discussed here. This project requires a good background in cosmology and astrophysics. The project can be seen as a continuation of project 3 and we will use again the Velocity Verlet algorithm.

We will try to build a simple model of an open cluster, as done by [M. Joyce and co-workers](#). An open cluster is a group of up to a few thousand gravitationally bound stars created from the collapse of a molecular cloud. This collapse leads to a flurry of star formation. Open clusters are usually found in the arms of spiral galaxies, or in irregular galaxies. Since stars in an open cluster have roughly the same age, and are made from the same material, they are interesting in the study of stellar evolution, since many of the variable parameters we have when comparing two stars are kept constant.

Once open clusters are formed they gradually dissipate as members get ejected from the cluster due to random collisions, this means that open clusters generally last only a few hundred million years. In the figure here we see the Hertzsprung-Russell diagrams for two open clusters.

We will study a simple model for how an open cluster is made from the gravitational collapse and interaction among a large number of stars. We want to study this collapse, and the statistical properties of the collapsed system. We will simulate what is called a *cold collapse*, this means that we start the particles with little or no initial velocity. You will also find it useful to start with the code you developed in project 3.

Project 5a): Extension of project 3. Extend your code from project 3 to an arbitrary number of particles, N , starting with a uniform (random) distribution within a sphere of a given radius R_0 . Start the particles at rest, with masses randomly distributed by a Gaussian distribution around ten solar masses with a standard deviation of one solar mass. Use solar masses and light years as units

Figure 1: Hertzsprung-Russell diagrams for two open clusters, M67 and NGC 188. We see that most of the stars are on the main sequence. In the older cluster, NGC 188, we see that the heaviest stars are just now leaving the main sequence, while the younger cluster, M67.

of mass and length and make your equations dimensionless. This function is included below and can be used to generate random numbers which follow a Gaussian (or normal) distribution. Alternatively, you can use the *random* class in c++ and generate random numbers according to the normal distribution.

How large time steps are required given $R_0 = 20$ ly (light years), and $N = 100$? Do we have any units of time that fit this timescale? In the limit where $N \rightarrow \infty$, keeping ρ_0 constant, we get a continuous fluid. In this case the system collapses into a singularity at a finite time $\tau_{\text{crunch}} = \sqrt{\frac{3\pi}{32G\rho_0}}$.

Why do we not observe this singularity in our model? Use τ_{crunch} as the unit of time, and find G in these units (G will become a function of the number of particles N , and the average mass of the particles, μ).

Project 5b): Time to reach equilibrium. Run the system for a few τ_{crunch} . Save the positions of the particles at different times to file. Does the system reach an equilibrium? How long time does this take?

Project 5c): Kinetic and potential energy. Make a function that calculates the kinetic and potential energy of the system. Is the energy conserved? Some of the particles are ejected from the system, how can we identify these particles from the energies we have calculated? How much of the energy of the system is taken away by particle ejection? How does this change with different values of N ? Are there still particles being ejected after the system reaches equilibrium?

Project 5d): Numerical instabilities. We will now introduce a smoothing function to take care of the numerical instability that arises when two of the particles come very close. There are a lot of ways of inserting such a smoothing, but we will just look at a very simple one. We will modify the Newtonian force law to make it finite at short ranges

$$F_{mod} = -\frac{GM_1M_2}{r^2 + \epsilon^2}.$$

The parameter ϵ is a *small* real constant. What should the value of this parameter be? Try out different values (which one gives you the best energy conservation?). Can we justify this correction to the pure Newtonian force by noting that our particles do not represent actual point particles but rather mass distributions of some finite extent? Does the addition of this correction change any of the results from the previous exercise?

Project 5e): Test of the virial theorem. Now we will look at the particles that are bound (not ejected). What is the distribution of potential and kinetic energy?

The virial theorem says that for a bound gravitational system in equilibrium we have

$$2\langle K \rangle = -\langle V \rangle,$$

where $\langle K \rangle$ is the average (over time) kinetic energy of the system and $\langle V \rangle$ is the average potential energy.

By the ergodic hypothesis we can take an ensemble average (average over a large system) instead of the time average.

Are your results consistent with the virial theorem?

Project 5f): Density of particles. Try to plot the radial density of the particles (the particle density as a function of radius) in the equilibrium state. How would you extract such an information from your calculations? (Hint: make a histogram for the radial particle density) What is the average distance? What is the standard deviation? Plot the radial distribution of particles.

Run the code for different number of initial particles, keeping the total mass constant. The interpretation of one particle as one or a few stars will not be useful any more when you increase the number of particles beyond a few thousand, however the analysis of gravitationally bound systems of many particles have

much broader applications than cold collapse of open clusters, so the results are still highly relevant. What is the average distance from the centre of the cluster as a function of N ?

The radial distribution of particles in this kind of cold collapse can often be fit very well with the simple expression

$$n(r) = \frac{n_0}{\left(1 + \left(\frac{r}{r_0}\right)^4\right)}.$$

Try to fit your data to this curve, what is the value n_0 and r_0 ? Can you find how these values depend on N ?

How many particles can you simulate?

Compare your results with those found in [M. Joyce and co-workers](#).

If you want, you can also compare your results to the well-known Navarro-Frenk-White profile

$$\rho(r) = \frac{\rho_0}{\frac{r}{r_0} \left(1 + \frac{r}{r_0}\right)^2}.$$

Does this give a better fit?

Introduction to numerical projects

Here follows a brief recipe and recommendation on how to write a report for each project.

- Give a short description of the nature of the problem and the eventual numerical methods you have used.
- Describe the algorithm you have used and/or developed. Here you may find it convenient to use pseudocoding. In many cases you can describe the algorithm in the program itself.
- Include the source code of your program. Comment your program properly.
- If possible, try to find analytic solutions, or known limits in order to test your program when developing the code.
- Include your results either in figure form or in a table. Remember to label your results. All tables and figures should have relevant captions and labels on the axes.
- Try to evaluate the reliability and numerical stability/precision of your results. If possible, include a qualitative and/or quantitative discussion of the numerical stability, eventual loss of precision etc.
- Try to give an interpretation of your results in your answers to the problems.
- Critique: if possible include your comments and reflections about the exercise, whether you felt you learnt something, ideas for improvements and other thoughts you've made when solving the exercise. We wish to keep this course at the interactive level and your comments can help us improve it.
- Try to establish a practice where you log your work at the computerlab. You may find such a logbook very handy at later stages in your work, especially when you don't properly remember what a previous test version of your program did. Here you could also record the time spent on solving the exercise, various algorithms you may have tested or other topics which you feel worthy of mentioning.

Format for electronic delivery of report and programs

The preferred format for the report is a PDF file. You can also use DOC or postscript formats or as an ipython notebook file. As programming language we prefer that you choose between C/C++, Fortran2008 or Python. The following prescription should be followed when preparing the report:

- Use Devilry to hand in your projects, log in at <http://devilry.ifi.uio.no> with your normal UiO username and password and choose either 'fys3150' or 'fys4150'. There you can load up the files within the deadline.
- Upload **only** the report file! For the source code file(s) you have developed please provide us with your link to your github domain. The report file should include all of your discussions and a list of the codes you have developed. Do not include library files which are available at the course homepage, unless you have made specific changes to them.
- In your git repository, please include a folder which contains selected results. These can be in the form of output from your code for a selected set of runs and input parameters.
- In this and all later projects, you should include tests (for example unit tests) of your code(s).
- Comments from us on your projects, approval or not, corrections to be made etc can be found under your Devilry domain and are only visible to you and the teachers of the course.

Finally, we encourage you to work two and two together. Optimal working groups consist of 2-3 students. For this specific report you can hand in a common report.
